A low-density hybridization-based approach to screening for carriers of long-tandem repeat disorders and point mutations. The long-tandem repeat (LTR) disorders include many inherited neurological disorders, which are usually diagnosed by their clinical presentation. However, only a fraction of affected individuals can be clinically diagnosed. In the absence of a molecular diagnosis, the only way to detect carriers of an LTR disorder is to use direct LTR sequencing with a repeat length of less than 45 base pairs. In addition, due to the frequency of long (approximately 200 base pairs) homopolymer LTR sequences, rapid methods are required for the diagnosis of common point mutations. Furthermore, genetic analysis has identified a high incidence of heterozygosity in current populations, especially in the LTR regions. As a result, the use of repeat-based screening protocols for identification of carriers has become increasingly important. We describe the adaptation of a strategy previously used for the screening of point mutations to the analysis of tandem repeats, including design of screening primers, screening of most common point mutations, and design of multiplex screening reactions. The screening protocol was applied to the analysis of repeat-length polymorphisms in the peripheral blood lymphocyte DNA of patients with spinocerebellar ataxia type 3 (SCA3), Friedreich's ataxia (FA), and hereditary spastic paraplegia (HSP), and the analysis of point mutations in the SCA3, spinocerebellar ataxia type 17 (SCA17), and HSP genes. The screening protocol is simple, rapid, and efficient and does not require high-quality sequencing data as input information.// Copyright 2011 The Go Authors.
